1 Background

- Methylation of genes involved in the oncogenic process is a key process contributing to tumor initiation and/or progression [4].
- Finding *Genes Regulated by Methylation* (GRM) can lead to a better understanding and be a guide to finding new drug targets.
- In cancer-related genes it is common to observe a decrease in gene expression associated with hypermethylation.
 - When methylation is low (“off”) the gene can express normally and its expression may be any value, low or high,
 - when methylation is medium or high (“on”), the expression of the gene will be *repressed* and its values will tend to be low .
- As a consequence relation plots depicting methylation and expression may show L-shape patterns so the strategy adopted will be to mine such plots and select those that have such a shape.

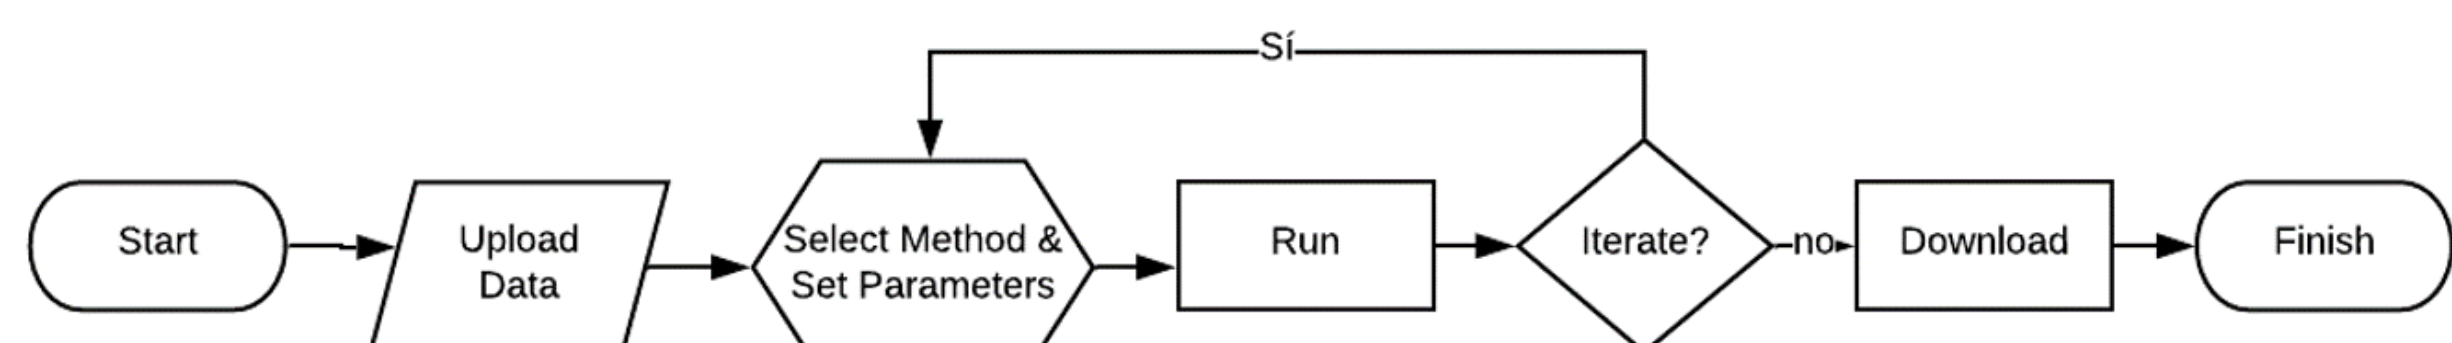

2 Results

- We developed a heuristic method based on imitating the visual selection of L-shapes by superimposing a 3×3 grid on the scatterplot ([5]).

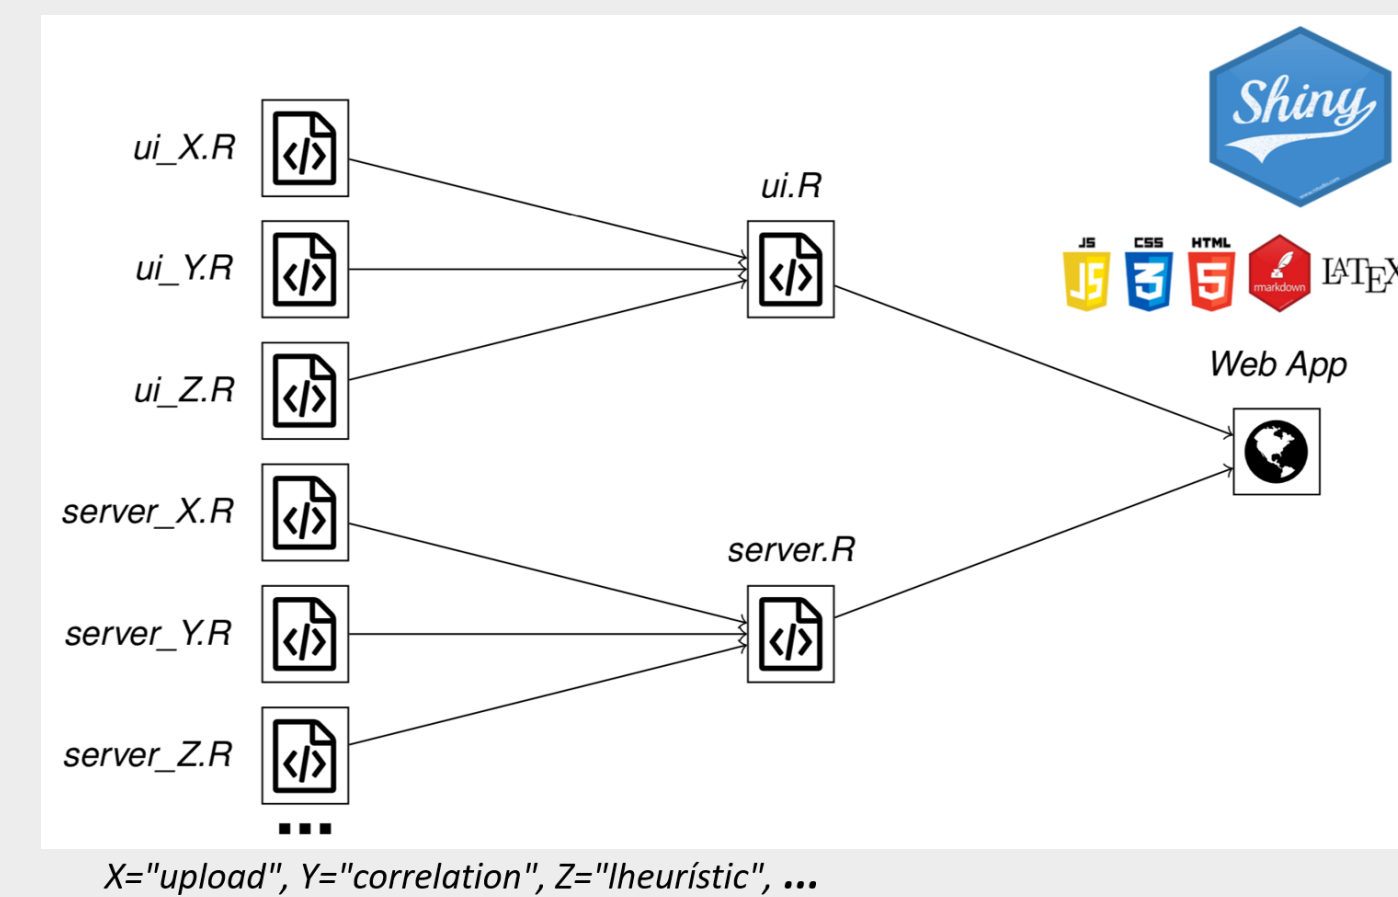

- The algorithm has been implemented in R (package ready-to-be-submitted to Bioconductor).
- A Shiny application has been created to select genes potentially regulated by methylation using a combination of the *Lheuristic* method and a *naïve* approach (negative correlation).
- Code is available in github:
<https://github.com/pcastellanoescuder/Lheuristic>
- The application is available in:
<http://cinna.upc.edu:3838/alex/lheuristic>

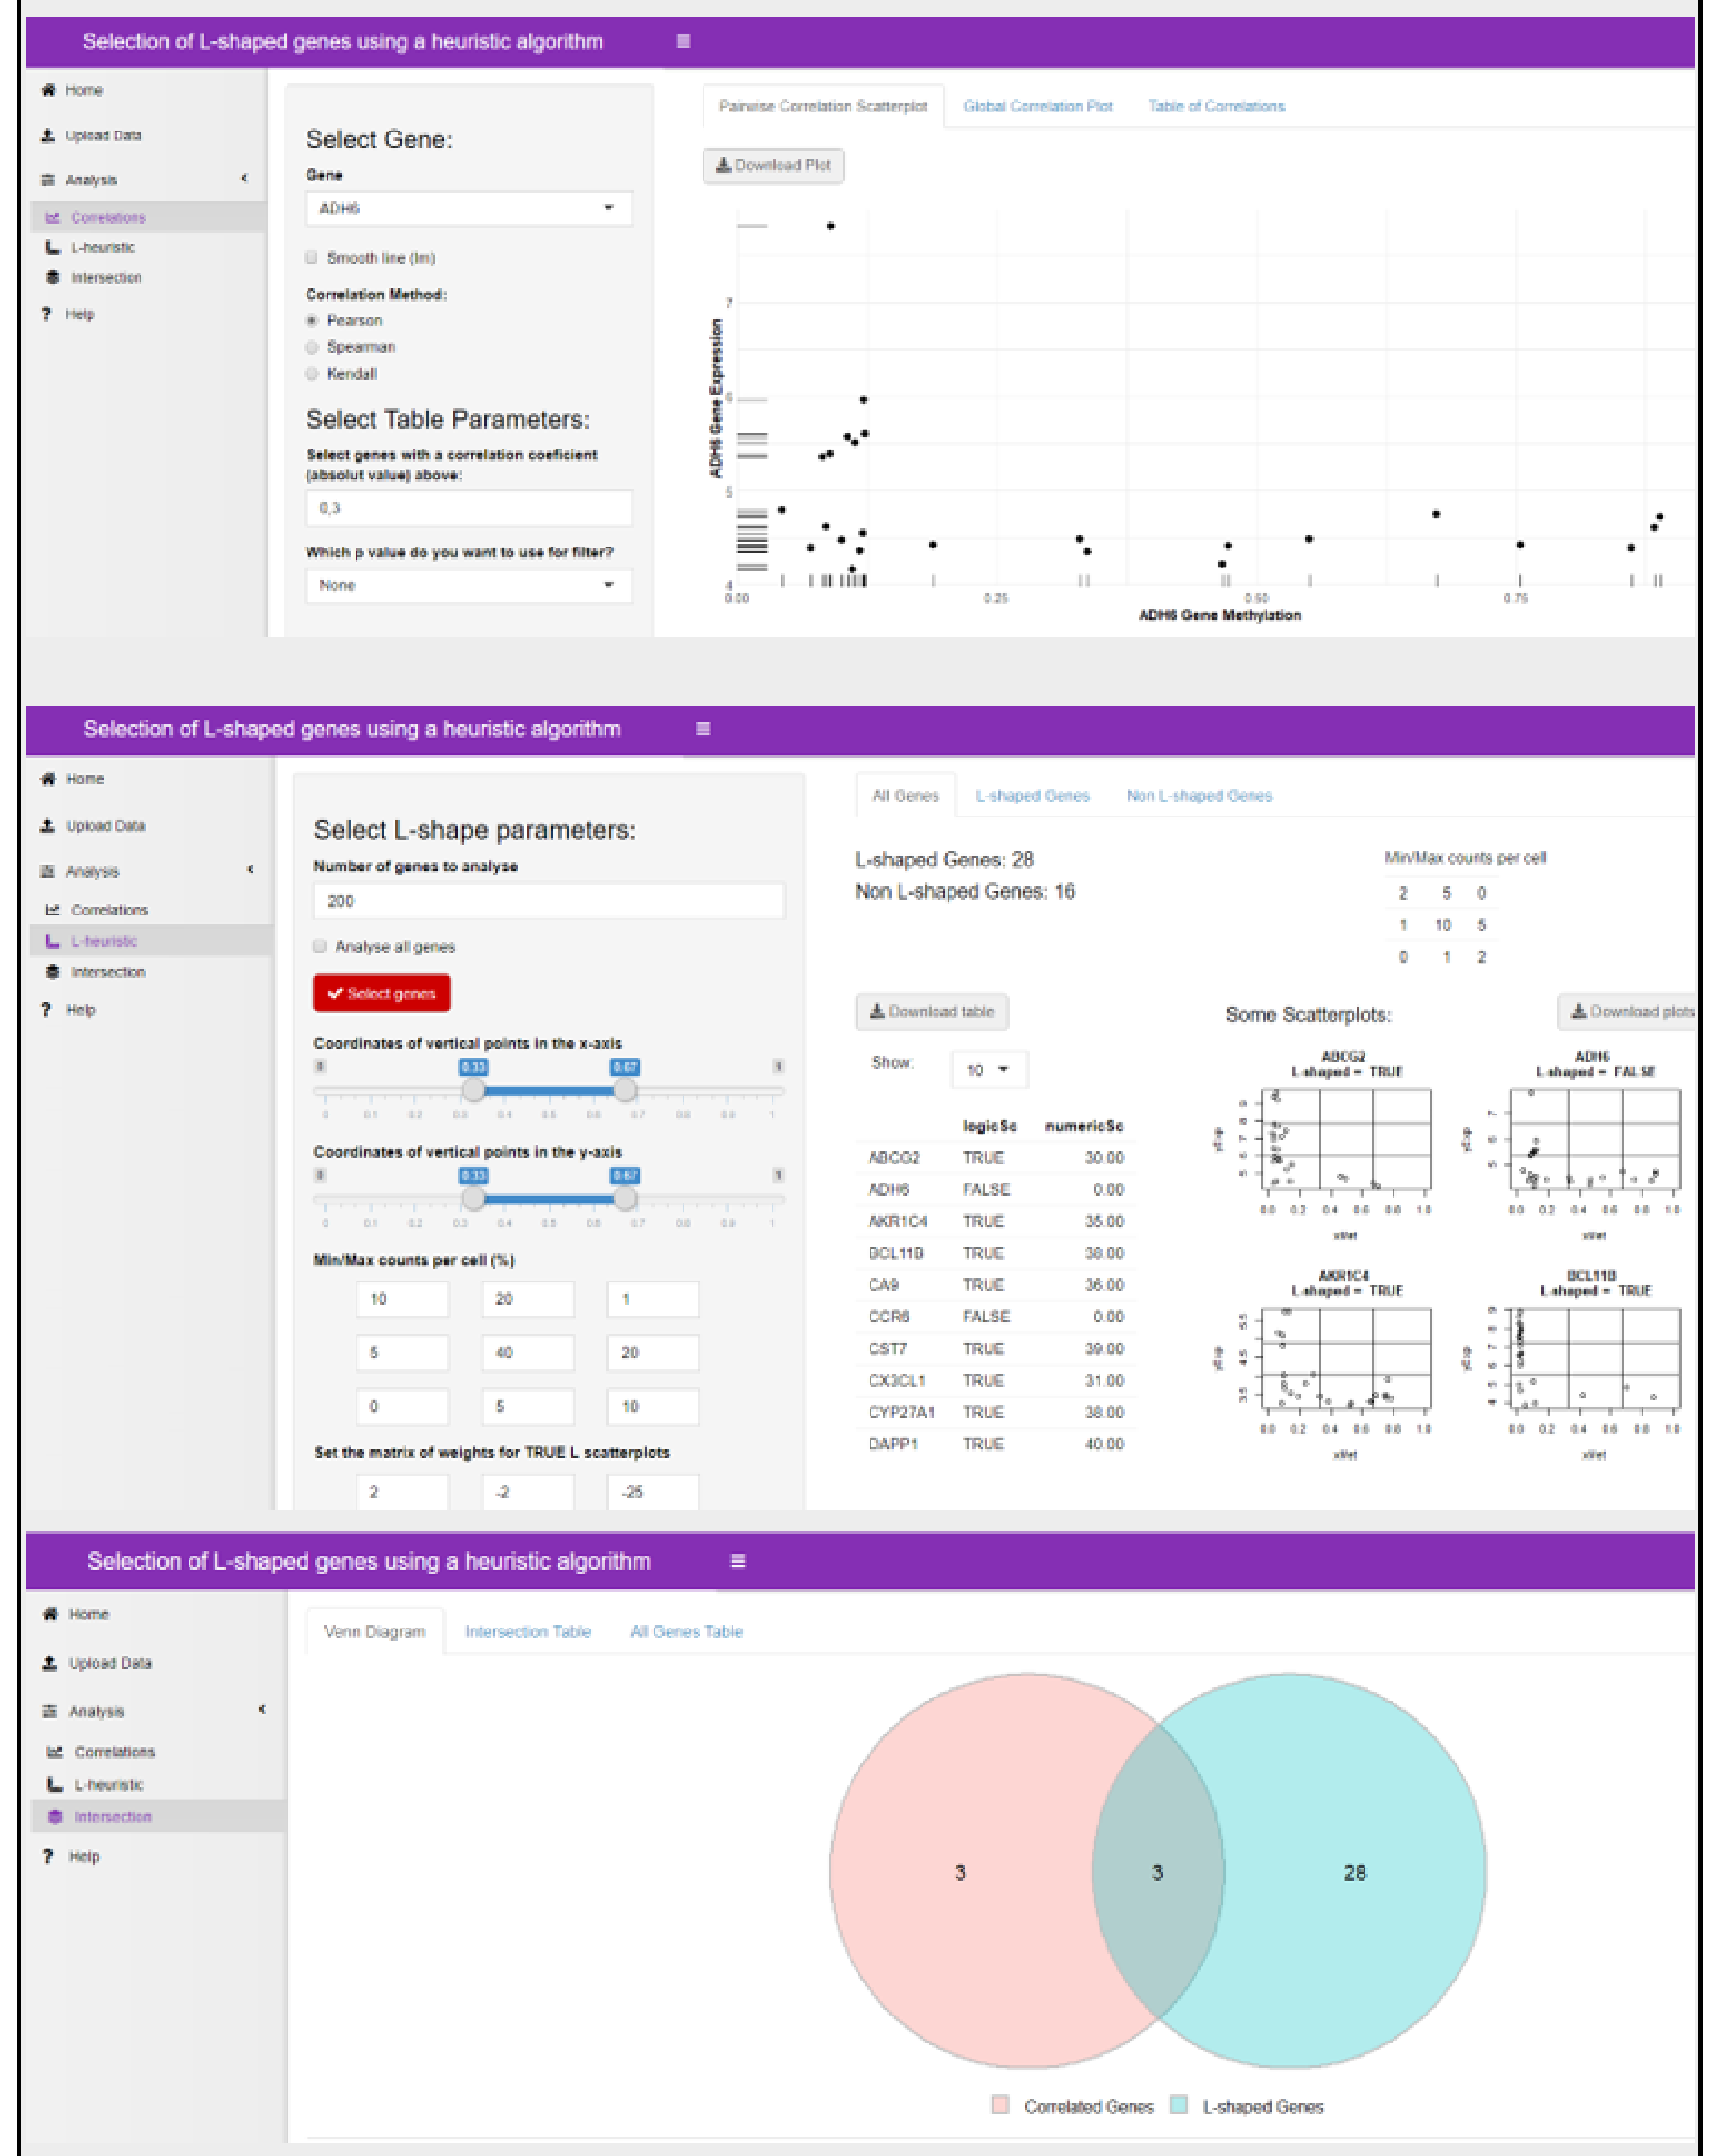

3 App Usage
